

PROTEIN-PROTEIN INTERACTIONS

Co-Immunoprecipitation vs Pull-Down

INTRODUCTION OF CO-IP AND PULL-DOWN

trolled by protein-protein interactions. Some dynamic characteristics of the intracellular proteins can be changed through the interactions. For example, substrate binding characteristics and catalytic activity can be changed; new binding sites are created and the specificity of a protein for a substrate is changed; some proteins can be inactivated to regulate the expression of other genes. Only when the protein-protein interactions are regulated can the normal cellular activities be carried out. Co-immunoprecipitation (Co-IP) and pull-down methods are related methods that are used to determine the stable protein-protein interactions.

Co-Immunoprecipitation

Co-immunoprecipitation detects the presence of specific interactions between two proteins in vitro. The principle of CO-IP is as follows: When cells are lysed under lular protein interactions are preserved. If if it's binding to protein X. By studying protein Y, an interaction between proteins X and Y can be confirmed.

Pull-Down

ty purification method that uses a bait protein to enrich proteins that interact with "pulled-down" when the target protein or cell lysate flows through. By subsequent Mass Spectrometry, a predicted interaction can be confirmed or previously unknown interactions can be discovered.

PRINCIPLE OF CO-IP AND PULL-DOWN

GST Pull-Down as an example.

PRINCIPLE OF CO-IP AND PULL-DOWN

	Co-IP	Pull-Down
Advantages	 Bait protein and prey protein are in natural conformation in CO-IP analysis. The interaction between bait and prey protein occurs in the body with little external influence. Does not require cloning and heterol- ogous expression. Rapid if antibody is available. 	 Generic ability to purify low-abundant protein complexes. The pull-down assay is general- ly used for in vitro transcription or translation systems.
Disadvantages	 Low affinity or transient interactions between proteins may not be detected. Co-IP results cannot determine whether the interaction is direct or indirect, as the possibility of other proteins participating cannot be ruled out. Not generic-requires access to specif- ics antibodies. 	 The presence of a protein tag may influence results competition with the endogenous complex. It doesn't really reflect the inter- actions between proteins, because they don't necessarily meet spatially in the body, so it doesn't mean that they're bound physiologically.
